Pseudocode for a **tidk** algorithm used in **tidk explore**. The algorithm is used to merge k-mers with the same minimal form. It explains the code written in the GitHub repository found **here**.

```
1: function MERGE_KMERS(hashmap)
2:   merged_hashmap  $\leftarrow$  {}
3:   for kmer, count in hashmap.items do
4:      $\triangleright$  Compute the minimal form for this kmer
5:     nimal_form  $\leftarrow$  compute_minimal_form(kmer)
6:      $\triangleright$  Merge counts using the minimal form as the key
7:     if minimal_form in merged_hashmap then
8:       merged_hashmap[minimal_form] + = count
9:     else
10:      merged_hashmap[minimal_form] = count
11:   return merged_hashmap

1: function COMPUTE-MINIMAL-FORM(kmer)
2:    $\triangleright$  Generate all rotations of the kmer
3:   rotations  $\leftarrow$  kmer[i:] + kmer[:i] for i in range(len(kmer))
4:
5:    $\triangleright$  Compute reverse complement of the kmer
6:   reverse_complement  $\leftarrow$  reverse_complement(kmer)
7:
8:    $\triangleright$  Generate all rotations of the reverse complement
9:   reverse_rotations  $\leftarrow$  reverse_complement[i:] + reverse_complement[:i] for i in
   range(len(reverse_complement))
10:
11:    $\triangleright$  Find the lexicographically minimal rotation (smallest in alphabetical order)
12:   minimal_form  $\leftarrow$  min(rotations + reverse_rotations)
13:
14:   return minimal_form
```
